

CSH and CSH-B 72.5 - 245 kV Horizontal Circuit Switcher

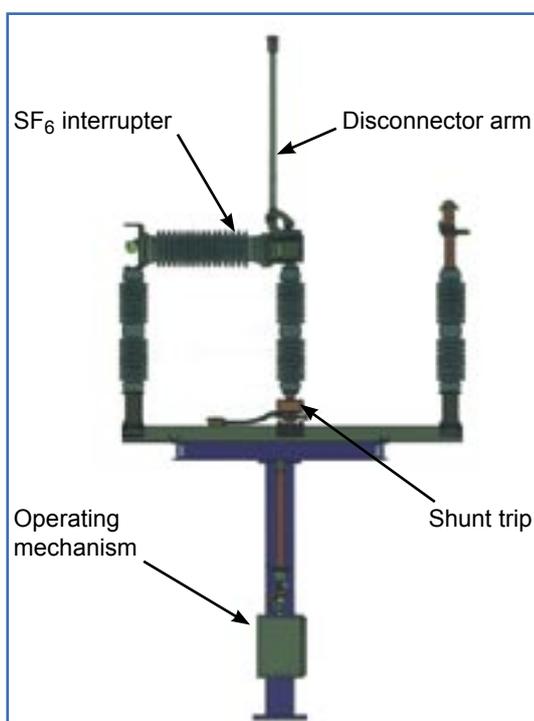

HV Switching

To switch, protect, and isolate transformers and loads

- **Through a unique, rugged package**
- **Through a single operation**
- **In the smallest space**

We know how

Our range of circuit and line switches provides an economical, versatile, space saving solution for fault protection and switching applications that require more than a disconnect, and where a conventional circuit breaker is not suitable. From our 50-year experience in HV grids, we offer tailored solutions in line with needs.

international standards (IEC, ANSI) and can be fitted with both types of insulators, but can also be customised according to particular specification.

The CSH / CSH-B Horizontal Circuit Switcher

The CSH Horizontal Circuit Switcher is made of three poles, operated simultaneously by a single operating mechanism. Pole simultaneity is achieved through the use of shunt trips on opening, and through mechanical interphase linkages on closing.

It is available in two versions :

- The Type CSH is the non-blade model, without built-in disconnector ;
- The Type CSH-B includes a Vertical Break disconnector, mounted in series, and synchronised with the chamber.

Both versions use the same SF₆ chamber, that is used to make and break on rated current, but also in fault condition. The CSH-B adds the appreciable feature of visible isolation in air.

Like all our models, the CSH meets the latest

Key features and applications

The CSH and CSH-B provide a versatile, space saving solution for fault protection and switching where rapid reclosing of the circuit is not desirable. It allows to switch :

- Transformers
- Reactors
- Lines
- Cables

The single gap SF₆ chamber needs no grading capacitor to maintain insulation, and is able to break the fault current within 4 to 6 cycles, depending on the voltage, and the power frequency. Compared to systems making in the air, this produces very few disturbances on the system.

The CSH-B offers the unique feature of combining SF₆ making and breaking with visible gap air insulation, in a single switching sequence and through a single operating mechanism. Therefore, no additional interlocking is necessary between switching and isolating devices, and both the reliability and the compactness of the bay are improved.

Like for any of our disconnectors, it is possible to fit 1 or 2 Earthing Switches on the CSH-B, and even some instrument transformers, to get a full, free-standing bay switchgear assembly.

Construction features

Each pole of CSH has one fixed insulator, and one rotary insulator that actuates the chamber. The CSH-B adds one fixed insulator to support the fixed contact of the disconnecter.

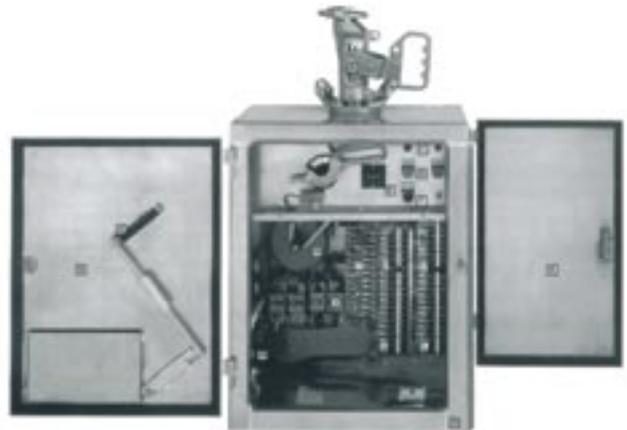

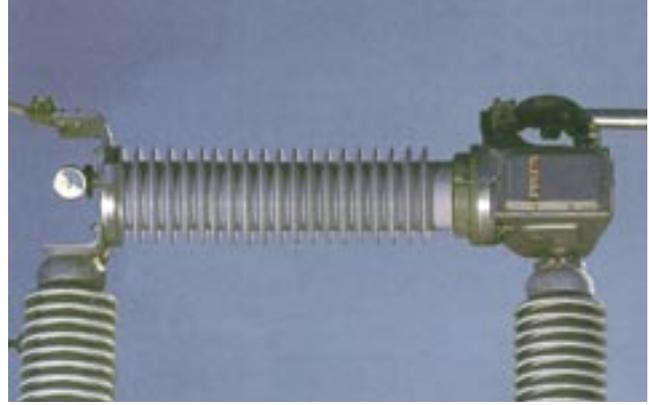

The chamber is a single-gap, puffer type, using SF₆ gas. It is housed in a horizontal hollow porcelain insulator. Its motion is made through purely mechanical means :

- Energy storage is made through opening and closing springs, housed in an aluminium casting located on top of the insulating rod.
- A shunt trip, located at the base of the rotary column, initiates the tripping operation, in the opening phase.
- The CSH / CSH-B is operated through a single disconnecter-type operating mechanism, supplying the necessary torque to charge the interrupter, and to operate the disconnecter for the CSH-B.

All conductive parts are made of copper or aluminium, and assembled with stainless steel hardware, while the contacts are made of solid copper, with silver plating where necessary. The HV terminals are made of aluminium.

The base frame and the rotary support are made of hot-dip galvanised steel profiles. The bearings are sealed and greased for a lifetime of maintenance free operation.

All our design and manufacturing process is ruled by ISO 9001 certified procedures to guarantee a perfect repeatability of the performances from the type-testing to the delivery of series.

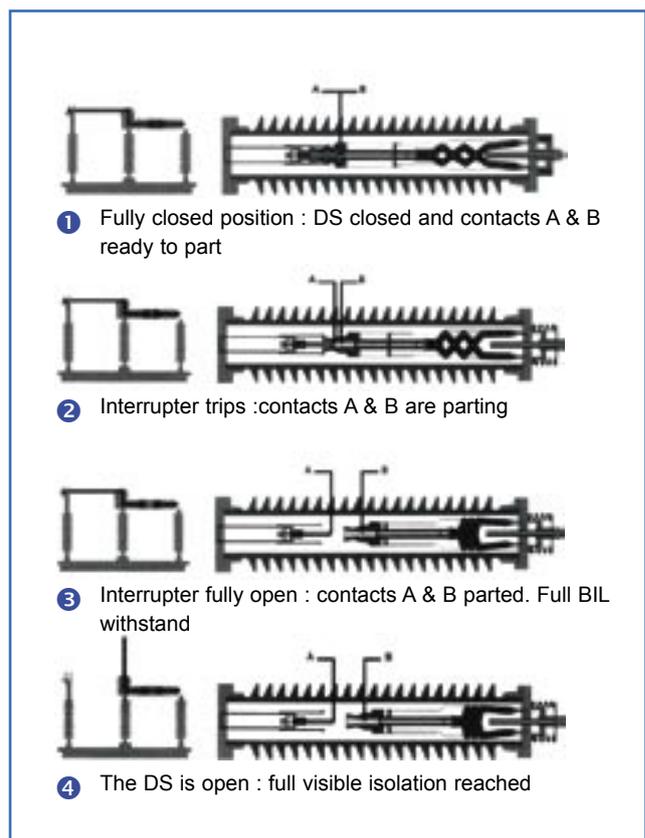

Operating principle

From the fully closed position **1** (both interrupter and DS are closed), a 12° rotation of the central insulator, initiated by the shunt trip or manual or motor operation, releases the opening springs in the driver mechanism, resulting in high speed opening **2** of the interrupter contacts, which allows to break the rated or fault current of the circuit.

After the interrupter has been fully opened **3** an additional 114° of rotation fully opens the disconnecter. Upon reaching the full open blade position **4**, the driver mechanism is reset for a closing sequence. Charging of the shunt trip occurs during the last 12° of opening rotation.

The closing sequence happens exactly in the reverse order : the rotation of the central insulator results in blade travel and charging of the interrupter closing springs in the driver mechanism.

The closing springs are released with the last few degrees of insulator rotation, closing the interrupter and charging the opening springs, while the disconnecter is already fully closed, thus, able to withstand the fault current of the circuit. Making the circuit in SF₆ prevents any damage on disconnecter contacts.

Ratings and dimensions

Rated voltage		Ur (kV)	72.5	123	145	170	245

Reliability and maintenance

Due to lifetime greased or self-lubricated hinges, and self-wiping contacts, the maintenance of the CSH metallic parts is ensured by its own motion. The use of corrosion-free or protected materials for all the components induces an exceptional reliability over many years of service. The mechanical endurance performance exceeds the IEC standard requirements.

Custom applications

The CSH / CSH-B is only one of the possible combinations of our switchers with disconnectors. Depending on the application, we can also provide combinations of horizontal chambers with Centre Break or Double Break disconnectors, or even similar combinations with vertical chambers.

Upon request, extended ratings on current making / breaking are also available.
